Where the *rain* went

The climate crisis doesn't just bring more heat: it redistributes the water. Compared with the rain they knew in 1979–2000, the same sky that now **floods the western Pacific** *is* **emptying over the atolls of the centre**. *Same ocean, different rain.*

22 territories in west → east order around the ring · the ocean lies inside the ring, the sky outside

the west fills up

14

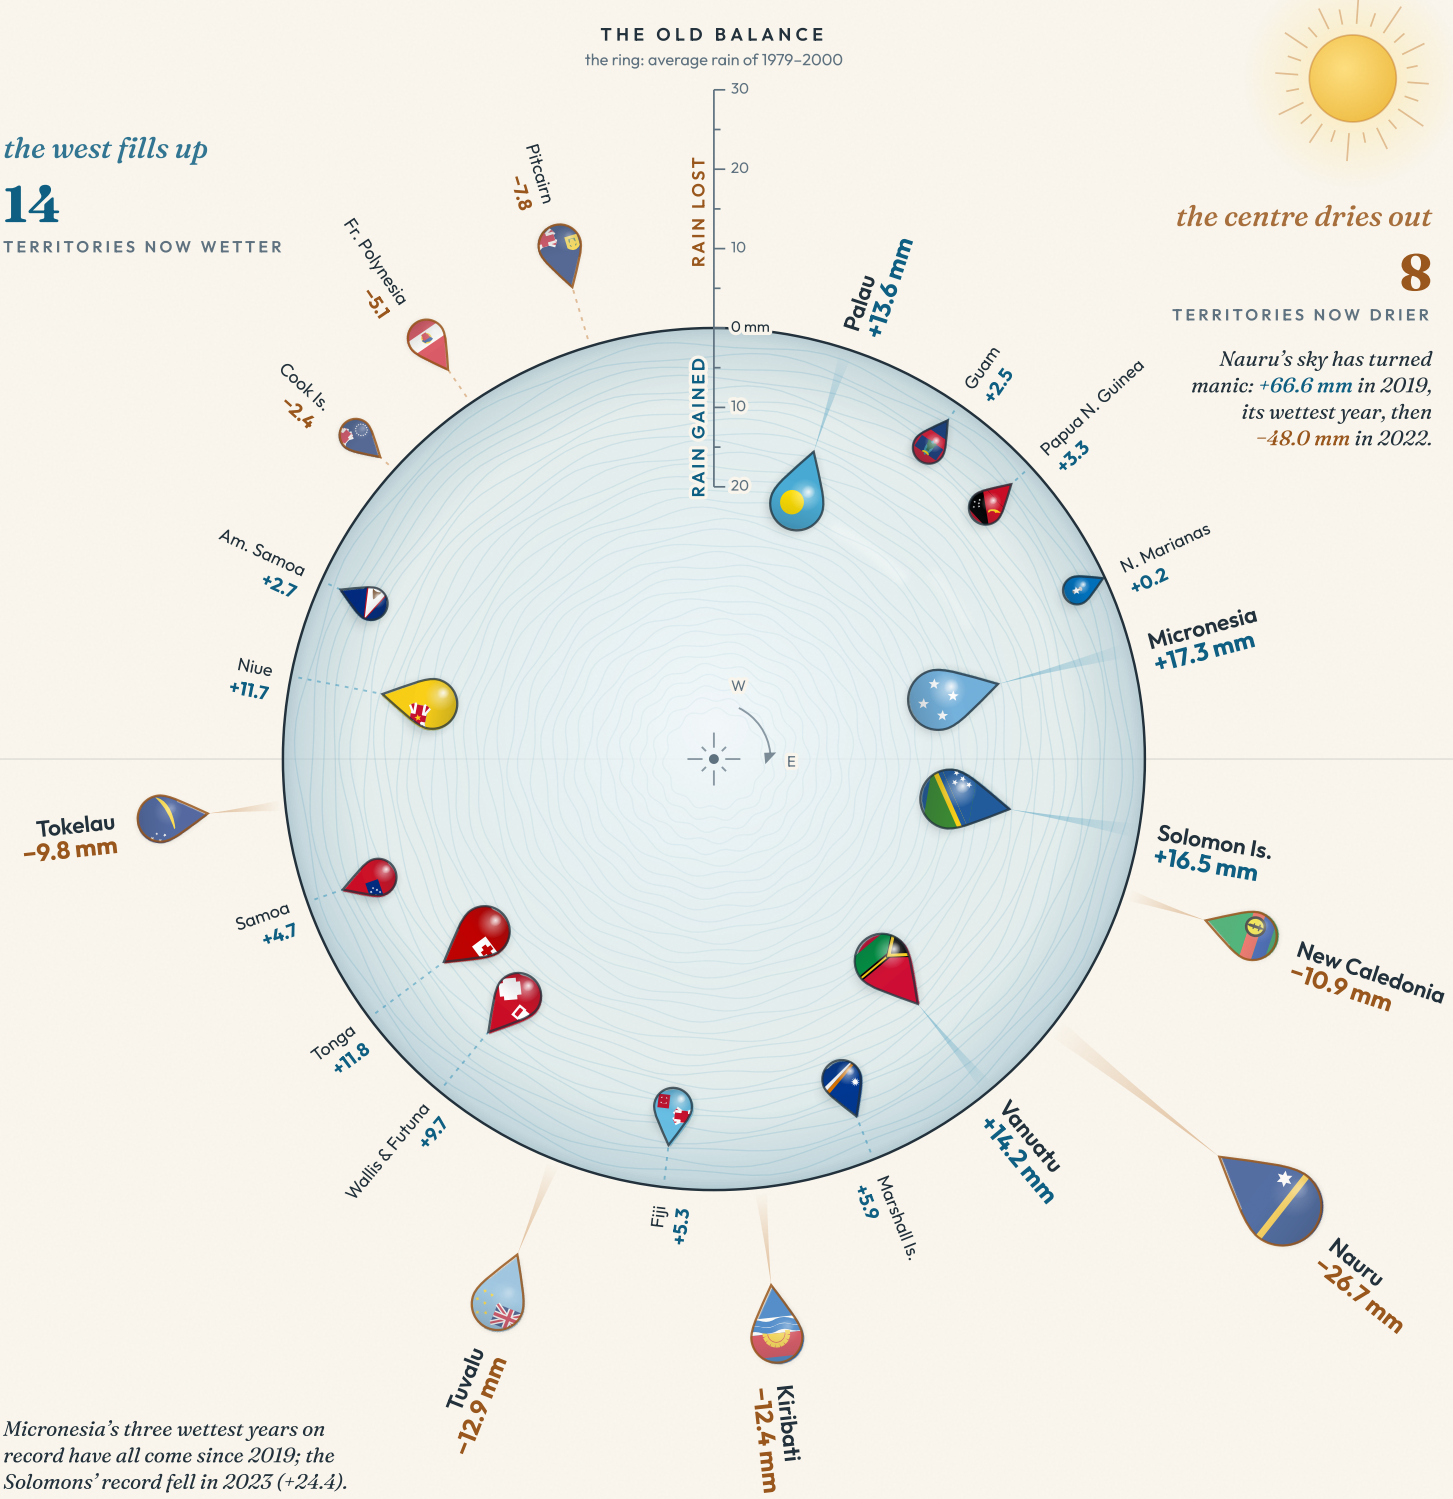

TERRITORIES NOW WETTER

the centre dries out

8

TERRITORIES NOW DRIER

Nauru's sky has turned manic: +66.6 mm in 2019, its wettest year, then −48.0 mm in 2022.

Micronesia's three wettest years on record have all come since 2019; the Solomons' record fell in 2023 (+24.4).

flag-drop falling inward = gaining rain; distance & size = shift, avg 2020–25 vs 1979–2000

faded drop rising = losing rain, evaporating back into the sky

the nine biggest shifts leave a streak, trailing from the old balance down to today's drop

Data: SPC Pacific Data Hub · annual rainfall anomalies (DF_CLIMATE_CHANGE, RAIN_ANOM, mm) · 22 Pacific Island countries and territories, 1979–2025
