Where the *rain* went

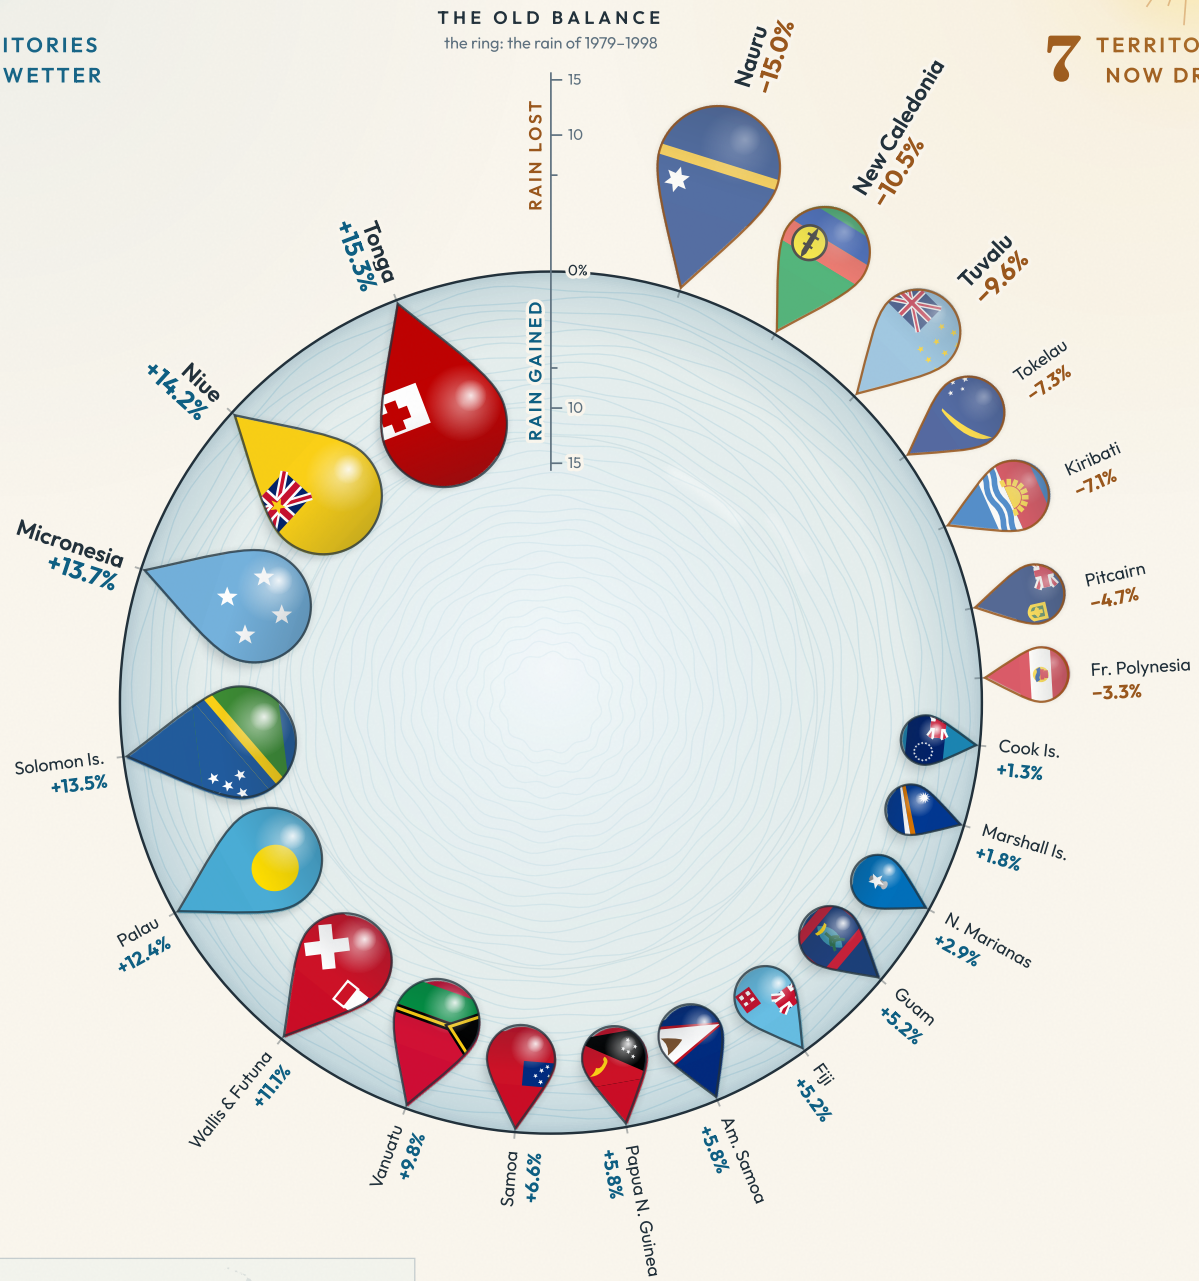

The climate crisis does more than warm the Pacific, it is redrawing where the rain falls. Around the ring of the old balance the 22 territories hang ordered by their shift, each one a flag drop sized by that shift in % of a normal year's rain. Rain arriving falls inward, into the ocean. Rain leaving rises outward, a faded drop evaporating back into the sky. From driest beneath the sun to wettest beyond the gap, **the west and south have grown wetter** *while* **the dateline atolls have run dry**. *Same ocean, different rain.*

where the rain moved in

where the rain is leaving

15 TERRITORIES NOW WETTER

7 TERRITORIES NOW DRIER

Back on the map, every **filled blue dot** *is a territory now gaining rain and every* **open amber ring** *is one losing it, each sized by the same shift.* **Tonga gains 15.3% more rain** *while* **Nauru has lost 15.0%**, *the same warming ocean pulling water in opposite directions. This is not ordinary variability, it is the climate crisis redrawing the Pacific's water map.*
