Where the *rain* went

The climate crisis doesn't just bring more heat: it redistributes the water. Between the record's first twenty years and its last twenty, the sky has tilted: it now **floods the west and south** *and* **empties the dateline atolls**. *Same ocean, different rain.*

22 territories ordered by their shift, driest beneath the sun, clockwise round to wettest · the ocean lies inside the ring, the sky outside

where the rain moved in

TERRITORIES NOW DRIER

Micronesia's three wettest years in 47 years have all come since 2019. The Solomons' record fell in 2023 (+24.4%).

Nauru's sky has turned manic: +66.6% in 2019, its wettest year since 1979, then −48.0% in 2022.

flag-drop falling inward = gaining rain, size = shift in % of normal rain, 2006–25 vs 1979–98

faded drop rising = losing rain, evaporating back into the sky

the nine biggest shifts hang from a solid thread, the others from a dotted one

Data: SPC Pacific Data Hub · annual rainfall anomalies in % of the 1991–2020 normal (DF_CLIMATE_CHANGE, RAIN_ANOM) · 22 Pacific territories, 1979–2025
The record's first twenty years against its last twenty, one generation apart. The same pattern runs through the full 47-year trend.
